This issue is often seen in various Linux distributions, leading to issues with NVIDIA driver installation.### Step 1: Verify the Running Kernel VersionFirst, it's essential to check which kernel version is currently being used. Open the terminal and run the command `uname -r` to find out the current kernel version.### Step 2: Remove Conflicting ModulesIf multiple kernel module versions are detected, try removing any conflicting modules. The command `sudo apt-get purge` (for Debian-based systems) or `sudo yum remove` (for RPM-based systems) can be used to remove the module.### Step 3: Install with DKMS ModuleThe recommended way to install NVIDIA drivers is using the DKMS module. This ensures that only one version of the kernel module is installed at a time, resolving conflicts. Use the command `sudo apt-get install nvidia-dkms` (for Debian-based systems) or `sudo yum install Nvidia-DKMS` (for RPM-based systems).### Step 4: Disable NouveauTo avoid conflicts with the Nouveau open-source driver, set it to be inactive using the following commands:``bashsudo apt-get remove Nouveausudo apt-get install bumblebysudo ln -s /etc/X11/xorg.conf.d/10-evergen.conf /etc/X11/xorg.conf.d/``Or (for RPM-based systems):``bashsudo yum remove Nouveausudo yum install bumblebysudo ln -s /usr/lib/rpm/libcomerr.so.2.5 /lib/libcomerr.so.2.5``### Step 5: Choose and Unify Kernel Module TypesTo ensure stability, it's crucial to select the correct kernel module type for your NVIDIA GPU. You can do this by setting the `LD_LIBRARY_PATH` environment variable to point to the correct driver library or by manually configuring the system.
